# *The Complex-Step Approximation*

## 1.1 Definition

Consider a scalar-valued function  $f : \mathbb{R} \rightarrow \mathbb{R}$ . The complex-step approximation to its derivative with respect to  $x$ , evaluated at  $x = x_0$ , is defined as [9, 12]

$$\left. \frac{df}{dx} \right|_{x=x_0} \approx \frac{\text{Im}[f(x_0 + ih)]}{h} \quad (1.1)$$

where  $h$  is the step size.

## 1.2 Implementation

As noted in Cleve Moler's blog post on the topic [11], the complex-step approximation converges to within double precision at a step size of about  $h \approx \sqrt{\varepsilon}$  (due to the  $\mathcal{O}(h^2)$  convergence), where  $\varepsilon$  represents double precision. Therefore, the implementation consists of just two steps: initializing  $h = \sqrt{\varepsilon}$ , and then approximating the derivative using Eq. (1.1). This procedure is formalized as Algorithm 1 below.

### Algorithm 1: `iderivative_s`

Derivative of a univariate, scalar-valued function using the complex-step approximation.

#### Given:

- $f(x)$  - univariate, scalar-valued function ( $f : \mathbb{R} \rightarrow \mathbb{R}$ )
- $x_0 \in \mathbb{R}$  - point at which to differentiate
- $h \in \mathbb{R}$  - (*OPTIONAL*) step size

#### Procedure:

1. Initialize the step size if not input.

$$h = \sqrt{\varepsilon}$$

2. Evaluate the derivative of  $f(x)$  at  $x_0$  using the complex-step approximation.

$$\left. \frac{df}{dx} \right|_{x=x_0} \approx \frac{\text{Im}[f(x_0 + ih)]}{h}$$

**Return:**

- $\left. \frac{df}{dx} \right|_{x=x_0} \in \mathbb{R}$  - derivative of  $f(x)$  evaluated at  $x = x_0$

**Note:** We precede all algorithm names with “i” to indicate that the algorithm is using the complex-step derivative approximation, where  $i$  is the imaginary unit.

## 1.3 Limitations

### 1.3.1 Higher-Order Derivatives

The complex-step approximation can be extended to second derivatives as

$$\left. \frac{d^2f}{dx^2} \right|_{x=x_0} \approx \frac{2(f(x_0) - \text{Re}[f(x_0 + ih)])}{h^2}$$

Unfortunately, unlike in the first derivative case, the second derivative approximation can introduce errors if the step size is made too small. Therefore, it can be tricky to implement for general nonlinear functions and we will use a different approach when evaluating second derivatives in Section 2.6.

Additionally, we cannot use nested calls on a complex-step differentiation algorithm to obtain higher-order derivatives. Consider trying to approximate a second derivative by nesting one complex-step approximation within another:

$$\left. \frac{d^2f}{dx^2} \right|_{x=x_0} \approx \left. \frac{d}{dx} \right|_{x=x_0} \left[ \frac{\text{Im}[f(x_0 + ih)]}{h} \right] \approx \frac{\text{Im} \left[ \overbrace{\frac{\text{Im}[f(x_0 + 2ih)]}{h}}^{\text{this term has no imaginary part}} \right]}{h}$$

Since the term in the bracket has no imaginary part, we would simply get

$$\left. \frac{d^2f}{dx^2} \right|_{x=x_0} = 0$$

which is incorrect.

### 1.3.2 Complexification

There are some special cases of functions where the complex-step approximation will not work directly; for example, trying to differentiate functions using MATLAB’s `atan2`, `atan2d`, `abs`, and `norm` functions would result in errors. The *Numerical Differentiation Toolbox* for MATLAB includes complexified versions of these specific functions (`iatan2`, `iatan2d`, `iabs`, and `inorm`), but a more exhaustive implementation has been programmed (in Fortran) and can be found in [2]. However, for MATLAB specifically, most differentiable functions are already suitable for use with the complex-step approximation [10].

The complexified version of `norm` is not included in [2], but it is essential for correctly computing partial derivatives and gradients of the 2-norm using the complex-step approximation. We know that for an arbitrary vector,  $\mathbf{v}$ , the 2-norm is defined as

$$\|\mathbf{v}\| = \sqrt{\mathbf{v}^T \mathbf{v}}$$

In the *Numerical Differentiation Toolbox*, we simply define the `inorm` function using this definition of the 2-norm. As discussed later in Section 1.4, it is essential in its implementation to use “`.'`” for the transpose operation as opposed to just “`'`” since the latter performs the Hermitian (conjugate) transpose.

### 1.3.3 Functions That Yield Incorrect Results

The following functions were tested in `iderivative_test` in the *Numerical Differentiation Toolbox* for MATLAB and yield incorrect results:

- `arccsc(x)` for  $x < -1$
- `arcsec(x)` for  $x < -1$
- `arccoth(x)` for  $0 < x < 1$
- `arctanh(x)` for  $x > 1$
- `arcsech(x)` for  $-1 < x < 0$
- `arccoth(x)` for  $-1 < x < 0$
- `arccosh(x)` for  $x < -1$
- `arctanh(x)` for  $x < -1$

Other functions that may yield errors due to lack of complexification are `max` and `min`; “complexified” versions of these can be found in [2] (as discussed in Section 1.3.2), but are *not* included in the *Numerical Differentiation Toolbox* for MATLAB.

## 1.4 Transposes

The transpose operation in MATLAB is typically performed using an apostrophe (`'`), but this is problematic because it actually performs the conjugate transpose (i.e. it also takes the complex conjugate of each element). Therefore, we must use a dot before the apostrophe (`.'`) to perform the non-conjugate transpose [10].

# *Differentiation Using the Complex-Step Approximation*

## **2.1 Derivative of a Univariate, Vector-Valued Function**

Consider a univariate, vector-valued function  $\mathbf{f} : \mathbb{R} \rightarrow \mathbb{R}^m$ . To approximate its derivative at a point  $x = x_0$ , we can begin by simply differentiating each component of  $\mathbf{f}$  with respect to  $x$  and evaluating the result at  $x = x_0$ .

$$\left. \frac{d\mathbf{f}}{dx} \right|_{x=x_0} = \begin{bmatrix} \left. \frac{df_1}{dx} \right|_{x=x_0} \\ \vdots \\ \left. \frac{df_m}{dx} \right|_{x=x_0} \end{bmatrix}$$

Applying the complex-step approximation to evaluate at  $x = x_0$ ,

$$\left. \frac{d\mathbf{f}}{dx} \right|_{x=x_0} \approx \begin{bmatrix} \frac{\text{Im}[f_1(x_0 + ih)]}{h} \\ \vdots \\ \frac{\text{Im}[f_m(x_0 + ih)]}{h} \end{bmatrix}$$

Therefore, in a more compact form, we can simply write

$$\boxed{\left. \frac{d\mathbf{f}}{dx} \right|_{x=x_0} \approx \frac{\text{Im}[\mathbf{f}(x_0 + ih)]}{h}} \quad (2.1)$$

For completeness, we include Algorithm 2. However, it should be noted that Algorithm 2 is nearly identical to Algorithm 1, except it is generalized to a vector-valued function  $\mathbf{f}$ .

**Algorithm 2: derivative**

Derivative of a univariate, vector-valued function using the complex-step approximation.

**Given:**

- $\mathbf{f}(x)$  - univariate, vector-valued function ( $\mathbf{f} : \mathbb{R} \rightarrow \mathbb{R}^m$ )
- $x_0 \in \mathbb{R}$  - point at which to differentiate
- $h \in \mathbb{R}$  - (OPTIONAL) step size

**Procedure:**

1. Initialize the step size if not input.

$$h = \sqrt{\varepsilon}$$

2. Evaluate the derivative of  $\mathbf{f}(x)$  at  $x = x_0$  using the complex-step approximation.

$$\left. \frac{d\mathbf{f}}{dx} \right|_{x=x_0} \approx \frac{\text{Im}[\mathbf{f}(x_0 + ih)]}{h}$$

**Return:**

- $\left. \frac{d\mathbf{f}}{dx} \right|_{x=x_0} \in \mathbb{R}^m$  - derivative of  $\mathbf{f}(x)$  evaluated at  $x_0$

**Note:**

- This function requires 1 evaluation of  $\mathbf{f}(x)$ .

## 2.2 Partial Derivative of a Multivariate, Scalar or Vector-Valued Function

Consider a multivariate, scalar-valued function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  where  $\mathbf{x} \in \mathbb{R}^n$  is the independent variable. The complex-step approximation for the partial derivative of  $f(\mathbf{x})$  with respect to  $x_j$ , evaluated at  $\mathbf{x} = \mathbf{x}_0$ , is

$$\left. \frac{\partial f}{\partial x_j} \right|_{\mathbf{x}=\mathbf{x}_0} \approx \frac{\text{Im} [f((x_{0,1}, x_{0,2}, \dots, x_{0,j} + ih, \dots, x_{0,n})^T)]}{h} \quad (2.2)$$

If we define

$$\chi_j = \begin{bmatrix} 0 \\ \vdots \\ ih \\ \vdots \\ 0 \end{bmatrix} \leftarrow j^{\text{th}} \text{ element} \quad (2.3)$$

then we can write the partial derivative in a more compact form as

$$\left. \frac{\partial f}{\partial x_j} \right|_{\mathbf{x}=\mathbf{x}_0} \approx \frac{\text{Im} [f(\mathbf{x}_0 + \chi_j)]}{h} \quad (2.4)$$

From Section 2.1, we know it is trivial to extend this to the vector-valued case ( $\mathbf{f} : \mathbb{R}^n \rightarrow \mathbb{R}^m$ ):

$$\left. \frac{d\mathbf{f}}{dx_j} \right|_{\mathbf{x}=\mathbf{x}_0} \approx \frac{\text{Im} [\mathbf{f}(\mathbf{x}_0 + \chi_j)]}{h} \quad (2.5)$$

In its implementation, we do not use  $\chi_j$  (although this term will be useful in later sections). Instead, within the function, we redefine  $\mathbf{x}_0$  as

$$\mathbf{x}_0 \leftarrow \mathbf{x}_0 + \chi_j$$

and then simply perform

$$\left. \frac{\partial \mathbf{f}}{\partial x_j} \right|_{\mathbf{x}=\mathbf{x}_0} \approx \frac{\text{Im}[\mathbf{f}(\mathbf{x}_0)]}{h}$$

### Algorithm 3: ipartial

Partial derivative of a multivariate, scalar or vector-valued function using the complex-step approximation.

#### Given:

- $\mathbf{f}(\mathbf{x})$  - multivariate, vector-valued function ( $\mathbf{f} : \mathbb{R}^n \rightarrow \mathbb{R}^m$ )
- $\mathbf{x}_0 \in \mathbb{R}^n$  - point at which to differentiate
- $j \in \mathbb{Z}$  - index of element of  $\mathbf{x}$  to differentiate with respect to
- $h \in \mathbb{R}$  - (OPTIONAL) step size

#### Procedure:

1. Initialize the step size if not input.

$$h = \sqrt{\varepsilon}$$

2. Redefine  $\mathbf{x}_0$  by updating its  $j^{\text{th}}$  element.

$$x_{0,j} = x_{0,j} + ih$$

3. Evaluate the partial derivative of  $\mathbf{f}(\mathbf{x})$  with respect to  $x_j$  at  $\mathbf{x} = \mathbf{x}_0$  using the complex-step approximation.

$$\left. \frac{\partial \mathbf{f}}{\partial x_j} \right|_{\mathbf{x}=\mathbf{x}_0} \approx \frac{\text{Im}[\mathbf{f}(\mathbf{x}_0)]}{h}$$

#### Return:

- $\left. \frac{\partial \mathbf{f}}{\partial x_j} \right|_{\mathbf{x}=\mathbf{x}_0} \in \mathbb{R}^m$  - partial derivative of  $\mathbf{f}(\mathbf{x})$  with respect to  $x_j$ , evaluated at  $\mathbf{x} = \mathbf{x}_0$

#### Note:

- This algorithm can be used for a scalar-valued function by just inputting a function where  $m = 1$  (i.e.  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  instead of  $\mathbf{f} : \mathbb{R}^n \rightarrow \mathbb{R}^m$ ).
- This function requires 1 evaluation of  $\mathbf{f}(\mathbf{x})$ .

## 2.3 Gradient

Consider a multivariate, scalar-valued function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$ . The gradient of  $f$  with respect to  $\mathbf{x} \in \mathbb{R}^n$ , evaluated at  $\mathbf{x} = \mathbf{x}_0$ , is defined as [4]

$$\mathbf{g}(\mathbf{x}_0) = \nabla f(\mathbf{x}_0) = \frac{\partial f}{\partial \mathbf{x}} \bigg|_{\mathbf{x}=\mathbf{x}_0} = \begin{bmatrix} \frac{\partial f}{\partial x_1} \bigg|_{\mathbf{x}=\mathbf{x}_0} \\ \vdots \\ \frac{\partial f}{\partial x_n} \bigg|_{\mathbf{x}=\mathbf{x}_0} \end{bmatrix} \quad (2.6)$$

To evaluate the gradient, we need to approximate all of the partial derivatives. From Eq. (2.4), we know the  $j^{\text{th}}$  partial derivative can be approximated as

$$\frac{\partial f}{\partial x_j} \approx \frac{\text{Im}[f(\mathbf{x} + \boldsymbol{\chi}_j)]}{h}$$

where

$$\boldsymbol{\chi}_j = \begin{bmatrix} 0 \\ \vdots \\ ih \\ \vdots \\ 0 \end{bmatrix} \leftarrow j^{\text{th}} \text{ element}$$

To make the computational implementation a bit neater and more efficient, we introduce the complex-step matrix,  $\mathbf{X}$ , defined as

$$\mathbf{X} = ih\mathbf{I}_{n \times n} = \begin{bmatrix} ih & \dots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \dots & ih \end{bmatrix} = \begin{bmatrix} | & & | \\ \boldsymbol{\chi}_1 & \dots & \boldsymbol{\chi}_n \\ | & & | \end{bmatrix} \quad (2.7)$$

As evident from Eq. (2.7),  $\boldsymbol{\chi}_j$  is simply the  $j^{\text{th}}$  column of  $\mathbf{X}$ . Now, we can develop the algorithm to approximate the gradient.

### Algorithm 4: igradient

Gradient of a multivariate, scalar-valued function using the complex-step approximation.

#### Given:

- $f(\mathbf{x})$  - multivariate, scalar-valued function ( $f : \mathbb{R}^n \rightarrow \mathbb{R}$ )
- $\mathbf{x}_0 \in \mathbb{R}^n$  - point at which to evaluate the gradient
- $h \in \mathbb{R}$  - (OPTIONAL) step size

#### Procedure:

1. Initialize the step size if not input.

$$h = \sqrt{\varepsilon}$$

2. Determine  $n$  from the fact that  $\mathbf{x}_0 \in \mathbb{R}^n$ .
3. Preallocate a vector  $\mathbf{g} \in \mathbb{R}^n$  to store the gradient.
4. Define the complex-step matrix.

$$\mathbf{X} = ih\mathbf{I}_{n \times n}$$

5. Evaluate the gradient.

```

for  $j = 1$  to  $n$ 
     $g_j = \frac{\text{Im}[f(\mathbf{x}_0 + \chi_j)]}{h}$  (where  $\chi_j$  is the  $j^{\text{th}}$  column of  $\mathbf{X}$ )
end

```

**Return:**

- $\mathbf{g} \in \mathbb{R}^n$  - gradient of  $f$  evaluated at  $\mathbf{x} = \mathbf{x}_0$

**Note:**

- This function requires  $n$  evaluations of  $f(\mathbf{x})$ .

## 2.4 Directional Derivative

Consider a multivariate, scalar-valued function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$ . The directional derivative of  $f$  at  $\mathbf{x} = \mathbf{x}_0$  in the direction of  $\mathbf{v} \in \mathbb{R}^n$  is [3]

$$D_{\mathbf{v}}f(\mathbf{x}_0) = \mathbf{v} \cdot \nabla f(\mathbf{x}_0) \quad (2.8)$$

Therefore, we can simply add a single additional line to Algorithm 4 to develop Algorithm 5 to calculate the directional derivative.

**Algorithm 5: idirectional**

Directional derivative of a multivariate, scalar-valued function using the complex-step approximation.

**Given:**

- $f(\mathbf{x})$  - multivariate, scalar-valued function ( $f : \mathbb{R}^n \rightarrow \mathbb{R}$ )
- $\mathbf{x}_0 \in \mathbb{R}^n$  - point at which to evaluate the directional derivative
- $\mathbf{v} \in \mathbb{R}^n$  - vector defining direction of differentiation
- $h \in \mathbb{R}$  - (*OPTIONAL*) step size

**Procedure:**

1. Initialize the step size if not input.

$$h = \sqrt{\varepsilon}$$

2. Determine  $n$  from the fact that  $\mathbf{x}_0 \in \mathbb{R}^n$ .
3. Preallocate a vector  $\mathbf{g} \in \mathbb{R}^n$  to store the gradient.
4. Define the complex-step matrix.

$$\mathbf{X} = ih\mathbf{I}_{n \times n}$$

5. Evaluate the gradient.

```

for  $j = 1$  to  $n$ 
     $g_j = \frac{\text{Im}[f(\mathbf{x}_0 + \chi_j)]}{h}$  (where  $\chi_j$  is the  $j^{\text{th}}$  column of  $\mathbf{X}$ )
end

```

6. Evaluate the directional derivative.

$$D_{\mathbf{v}} = \mathbf{v} \cdot \mathbf{g}$$

**Return:**

- $D_{\mathbf{v}} \in \mathbb{R}$  - directional derivative of  $f$  evaluated at  $\mathbf{x} = \mathbf{x}_0$  in the direction of  $\mathbf{v}$

**Note:**

- This function requires  $n$  evaluations of  $f(\mathbf{x})$ .

## 2.5 Jacobian Matrix

The Jacobian matrix of a multivariate, vector-valued function  $\mathbf{f} : \mathbb{R}^n \rightarrow \mathbb{R}^m$  with respect to  $\mathbf{x} \in \mathbb{R}^n$ , evaluated at  $\mathbf{x} = \mathbf{x}_0$ , is defined as

$$\mathbf{J}(\mathbf{x}_0) = \left. \frac{\partial \mathbf{f}}{\partial \mathbf{x}} \right|_{\mathbf{x}=\mathbf{x}_0} = \begin{bmatrix} \left. \frac{\partial f_1}{\partial x_1} \right|_{\mathbf{x}=\mathbf{x}_0} & \cdots & \left. \frac{\partial f_1}{\partial x_n} \right|_{\mathbf{x}=\mathbf{x}_0} \\ \vdots & \ddots & \vdots \\ \left. \frac{\partial f_m}{\partial x_1} \right|_{\mathbf{x}=\mathbf{x}_0} & \cdots & \left. \frac{\partial f_m}{\partial x_n} \right|_{\mathbf{x}=\mathbf{x}_0} \end{bmatrix} \quad (2.9)$$

It is helpful to rewrite Eq. (2.9) in terms of its column vectors as [8]

$$\mathbf{J}(\mathbf{x}_0) = \begin{bmatrix} \left. \frac{\partial \mathbf{f}}{\partial x_1} \right|_{\mathbf{x}=\mathbf{x}_0} & \cdots & \left. \frac{\partial \mathbf{f}}{\partial x_n} \right|_{\mathbf{x}=\mathbf{x}_0} \end{bmatrix} \quad (2.10)$$

From Eq. (2.5), we know

$$\left. \frac{\partial \mathbf{f}}{\partial x_j} \right|_{\mathbf{x}=\mathbf{x}_0} \approx \frac{\text{Im}[\mathbf{f}(\mathbf{x}_0 + \chi_j)]}{h}$$

where

$$\chi_j = \begin{bmatrix} 0 \\ \vdots \\ ih \\ \vdots \\ 0 \end{bmatrix} \leftarrow j^{\text{th}} \text{ element}$$

Utilizing Eq. (2.10), we only need to make a small adjustment to Algorithm 4 to develop Algorithm 6 for evaluating the Jacobian using the complex-step approximation.

### Algorithm 6: ijacobian

Jacobian matrix of a multivariate, vector-valued function using the complex-step approximation.

**Given:**

- $\mathbf{f}(\mathbf{x})$  - multivariate, vector-valued function ( $\mathbf{f} : \mathbb{R}^n \rightarrow \mathbb{R}^m$ )
- $\mathbf{x}_0 \in \mathbb{R}^n$  - point at which to evaluate the Jacobian matrix
- $h \in \mathbb{R}$  - (OPTIONAL) step size

**Procedure:**

1. Initialize the step size if not input.

$$h = \sqrt{\varepsilon}$$

2. Determine  $m$  from the fact that  $\mathbf{f}(\mathbf{x}_0) \in \mathbb{R}^m$ .
3. Determine  $n$  from the fact that  $\mathbf{x}_0 \in \mathbb{R}^n$ .
4. Preallocate a matrix  $\mathbf{J} \in \mathbb{R}^{m \times n}$  to store the Jacobian.
5. Define the complex-step matrix.

$$\mathbf{X} = ih\mathbf{I}_{n \times n}$$

6. Evaluate the Jacobian matrix (where  $\mathbf{j}_j$  is the  $j^{\text{th}}$  column vector of  $\mathbf{J}$ ).

$$\begin{array}{l} \text{for } j = 1 \text{ to } n \\ \quad \mathbf{j}_j = \frac{\text{Im}[f(\mathbf{x}_0 + \chi_j)]}{h} \quad (\text{where } \chi_j \text{ is the } j^{\text{th}} \text{ column of } \mathbf{X}) \\ \text{end} \end{array}$$

**Return:**

- $\mathbf{J} \in \mathbb{R}^{m \times n}$  - Jacobian matrix of  $\mathbf{f}$  evaluated at  $\mathbf{x} = \mathbf{x}_0$

**Note:**

- This function requires  $n$  evaluations of  $\mathbf{f}(\mathbf{x})$ .

## 2.6 Hessian Matrix

The Hessian matrix of a multivariate, scalar-valued function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  with respect to  $\mathbf{x} \in \mathbb{R}^n$ , evaluated at  $\mathbf{x} = \mathbf{x}_0$ , is defined as

$$\mathbf{H}(\mathbf{x}_0) = \begin{bmatrix} \left. \frac{\partial^2 f}{\partial x_1^2} \right|_{\mathbf{x}=\mathbf{x}_0} & \left. \frac{\partial^2 f}{\partial x_1 \partial x_2} \right|_{\mathbf{x}=\mathbf{x}_0} & \cdots & \left. \frac{\partial^2 f}{\partial x_1 \partial x_n} \right|_{\mathbf{x}=\mathbf{x}_0} \\ \left. \frac{\partial^2 f}{\partial x_2 \partial x_1} \right|_{\mathbf{x}=\mathbf{x}_0} & \left. \frac{\partial^2 f}{\partial x_2^2} \right|_{\mathbf{x}=\mathbf{x}_0} & \cdots & \left. \frac{\partial^2 f}{\partial x_2 \partial x_n} \right|_{\mathbf{x}=\mathbf{x}_0} \\ \vdots & \vdots & \ddots & \vdots \\ \left. \frac{\partial^2 f}{\partial x_n \partial x_1} \right|_{\mathbf{x}=\mathbf{x}_0} & \left. \frac{\partial^2 f}{\partial x_n \partial x_2} \right|_{\mathbf{x}=\mathbf{x}_0} & \cdots & \left. \frac{\partial^2 f}{\partial x_n^2} \right|_{\mathbf{x}=\mathbf{x}_0} \end{bmatrix} \quad (2.11)$$

In a more compact form, we can write

$$[\mathbf{H}(\mathbf{x}_0)]_{j,k} = \frac{\partial^2 f}{\partial x_j \partial x_k} \quad (2.12)$$

From Schwarz's theorem, we know

$$\frac{\partial^2 f}{\partial x_j \partial x_k} = \frac{\partial^2 f}{\partial x_k \partial x_j}$$

which implies that the Hessian matrix is symmetric and satisfies the property [6]

$$[\mathbf{H}(\mathbf{x}_0)]_{j,k} = [\mathbf{H}(\mathbf{x}_0)]_{k,j} \quad (2.13)$$

As mentioned in Section 1.3.1, we will not be using a true complex-step approximation for the second derivative in this section. Instead, we will evaluate the first derivative using a complex-step approximation, and the second derivative using a central difference approximation. Beginning by rewriting Eq. (2.12) in a slightly different form,

$$[\mathbf{H}(\mathbf{x}_0)]_{j,k} = \frac{\partial}{\partial x_j} \bigg|_{\mathbf{x}=\mathbf{x}_0} \left( \frac{\partial f}{\partial x_k} \bigg|_{\mathbf{x}=\mathbf{x}_0} \right)$$

Replacing the derivative in the parentheses with its complex-step approximation (from Eq. (2.4)), we can write

$$[\mathbf{H}(\mathbf{x}_0)]_{j,k} \approx \frac{\partial}{\partial x_j} \bigg|_{\mathbf{x}=\mathbf{x}_0} \left( \frac{\text{Im}[f(\mathbf{x}_0 + \boldsymbol{\chi}_k)]}{h} \right) \quad (2.14)$$

where

$$\boldsymbol{\chi}_k = \begin{bmatrix} 0 \\ \vdots \\ ih \\ \vdots \\ 0 \end{bmatrix} \leftarrow k^{\text{th}} \text{ element}$$

The central difference approximation to a derivative is [13]

$$\frac{df}{dx} \bigg|_{x=x_0} \approx \frac{f(x_0 + h) - f(x_0 - h)}{2h}$$

For a multivariate function, this can be written as

$$\frac{\partial f}{\partial x_j} \bigg|_{\mathbf{x}=\mathbf{x}_0} \approx \frac{f(\mathbf{x}_0 + \mathbf{u}_j) - f(\mathbf{x}_0 - \mathbf{u}_j)}{2h} \quad (2.15)$$

where

$$\mathbf{u}_j = \begin{bmatrix} 0 \\ \vdots \\ h \\ \vdots \\ 0 \end{bmatrix} \leftarrow j^{\text{th}} \text{ element} \quad (2.16)$$

Applying the approximation from Eq. (2.15) to Eq. (2.14),

$$\begin{aligned} [\mathbf{H}(\mathbf{x}_0)]_{j,k} &\approx \frac{1}{2h} \left[ \left( \frac{\text{Im}[f(\mathbf{x}_0 + \boldsymbol{\chi}_k + \mathbf{u}_j)]}{h} \right) - \left( \frac{\text{Im}[f(\mathbf{x}_0 + \boldsymbol{\chi}_k - \mathbf{u}_j)]}{h} \right) \right] \\ &\approx \frac{\text{Im}[f(\mathbf{x}_0 + \boldsymbol{\chi}_k + \mathbf{u}_j)] - \text{Im}[f(\mathbf{x}_0 + \boldsymbol{\chi}_k - \mathbf{u}_j)]}{2h^2} \\ &\approx \frac{\text{Im}[f(\mathbf{x}_0 + \boldsymbol{\chi}_k + \mathbf{u}_j) - f(\mathbf{x}_0 + \boldsymbol{\chi}_k - \mathbf{u}_j)]}{2h^2} \end{aligned}$$

Finally, let's define

$$\mathbf{x}_{r,k} = \mathbf{x}_0 + \boldsymbol{\chi}_k \quad (2.17)$$

$$\mathbf{y}_{j,k}^+ = \mathbf{x}_{r,k} + \mathbf{u}_j \quad (2.18)$$

$$\mathbf{y}_{j,k}^- = \mathbf{x}_{r,k} - \mathbf{u}_j \quad (2.19)$$

Then we arrive at the result

$$[\mathbf{H}(\mathbf{x}_0)]_{j,k} = [\mathbf{H}(\mathbf{x}_0)]_{k,j} \approx \frac{\text{Im} \left[ f(\mathbf{y}_{j,k}^+) - f(\mathbf{y}_{j,k}^-) \right]}{2h^2} \quad (2.20)$$

Similar to the complex-step matrix  $\mathbf{X}$ , we define the real-step matrix  $\mathbf{U}$  as

$$\mathbf{U} = h\mathbf{I}_{n \times n} = \begin{bmatrix} h & \dots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \dots & h \end{bmatrix} = \begin{bmatrix} | & & | \\ \mathbf{u}_1 & \dots & \mathbf{u}_n \\ | & & | \end{bmatrix} \quad (2.21)$$

With these definitions, we can develop Algorithm 7 below<sup>1</sup>. Since the Hessian matrix is symmetric, we only have to evaluate the derivatives in the upper triangle of the matrix (shown in red below):

$$\begin{bmatrix} H_{1,1} & H_{1,2} & \dots & H_{1,n} \\ H_{2,1} & H_{2,2} & \dots & H_{2,n} \\ \vdots & \vdots & \ddots & \vdots \\ H_{n,1} & H_{n,2} & \dots & H_{n,n} \end{bmatrix}$$

#### Algorithm 7: ihessian

Hessian matrix of a multivariate, scalar-valued function using the complex-step and central difference approximations.

##### Given:

- $f(\mathbf{x})$  - multivariate, scalar-valued function ( $f : \mathbb{R}^n \rightarrow \mathbb{R}$ )
- $\mathbf{x}_0 \in \mathbb{R}^n$  - point at which to evaluate the Hessian matrix
- $h \in \mathbb{R}$  - (OPTIONAL) step size

##### Procedure:

1. Initialize the step size if not input.

$$h = \sqrt{\varepsilon}$$

2. Determine  $n$  from the fact that  $\mathbf{x}_0 \in \mathbb{R}^n$ .
3. Preallocate a matrix  $\mathbf{H} \in \mathbb{R}^{n \times n}$  to store the Hessian.
4. Define the complex-step and real-step matrices.

$$\mathbf{X} = ih\mathbf{I}_{n \times n}$$

$$\mathbf{U} = h\mathbf{I}_{n \times n}$$

5. Loop over each independent variable.

**for**  $k = 1$  **to**  $n$

<sup>1</sup> This algorithm was inspired by [1] and [5].

- (a) Define the reference point with the complex increment in the  $k^{\text{th}}$  independent variable.

$$\mathbf{x}_r = \mathbf{x}_0 + \chi_k$$

- (b) Loop through the upper triangular elements.

**for**  $j = k$  **to**  $n$

- i. Define the reference points with the real increments in the  $j^{\text{th}}$  independent variable.

$$\mathbf{y}^+ = \mathbf{x}_r + \mathbf{u}_j$$

$$\mathbf{y}^- = \mathbf{x}_r - \mathbf{u}_j$$

- ii. Evaluate the  $(k, j)^{\text{th}}$  element of the Hessian.

$$H_{k,j} \approx \frac{\text{Im}[f(\mathbf{y}^+) - f(\mathbf{y}^-)]}{2h^2}$$

- iii. Evaluate the  $(j, k)^{\text{th}}$  element of the Hessian using symmetry.

$$H_{j,k} = H_{k,j}$$

**end**

**end**

**Return:**

- $\mathbf{H} \in \mathbb{R}^{n \times n}$  - Hessian matrix of  $f$  evaluated at  $\mathbf{x} = \mathbf{x}_0$

**Note:**

- $\chi_k$  is the  $k^{\text{th}}$  column of  $\mathbf{X}$  and  $\mathbf{u}_j$  is the  $j^{\text{th}}$  column of  $\mathbf{U}$ .
- This function requires  $n(n+1)$  evaluations of  $f(\mathbf{x})$  (the upper triangular matrix entries (including the diagonal) consist of  $n(n+1)/2$  entries [7], and each entry requires 2 evaluations of  $f(\mathbf{x})$ ).
